ABSTRACT – In this present study, three insitu composites have been produced with different reinforcement of Al(Zr, ZrB) and Al(Zr+ZrB) in AA5052 alloy matrix by direct melt reaction (DMR) technique. These composites were characterized by XRD for phases present, for morphology under SEM. Mechanical properties have been evaluated in detail and tribological properties have been studied under dry sliding wear conditions for all composites for different variables such as sliding distance and applied loads. XRD and SEM results show the successful formation of reinforcements. The mechanical and wear test results shows that Al(Zr+ZrB) reinforced AA5052 composite has the superior mechanical properties and wear resistance among all composites. This composite could be a suitable substitute for existing materials for applications related to automobile, aero-space and marine applications.

1. INTRODUCTION

Aluminium matrix composites (AMCs) exhibit superior specific strength, specific modulus, damping capacity and wear resistance as compared to monolithic materials [1]. Al-Mg alloy has moderate-to-high-strength, work-hardenable, good welding characteristics and high resistance to corrosion in marine environment [2]. Al(Zr and ZrB) are considered as potential reinforcements to this alloy because Al(Zr has low density, high melting point and high elastic modulus with excellent resistance to oxidation and corrosion [3] while ZrB exhibits unique combination of mechanical and physical properties, high melting points, good thermal and electrical conductivities [4].

Based on above mention properties of base alloy and reinforcement, in this present study, three composites have been fabricated with different reinforcement Al(Zr, ZrB and Al(Zr+ZrB) by DMR technique. These composites are characterized for morphology, mechanical and tribological properties under dry sliding conditions.

2. METHODOLOGY

In the present study, the starting material was AA5052 alloy and inorganic salts K2ZrF6, KBF4. Initially, inorganic salts were pre-heated in an electric oven at 250°C for 3 hours to eliminate the moisture content, simultaneously, AA5052 alloy was brought to melt condition and heated to 885°C temperature in the graphite crucible kept in vertical muffle furnace. The dehydrated powders were added in required amount while stirring the melt until insitu reaction was complete and melt was bottom poured into a mild steel mould. The composition of as cast composites with designation is shown in Table 1.

The phases present in the composites were identified by Rigaku Miniflex II X-ray diffractometer. FESEM Quanta 200FEG scanning-electron microscope (SEM) was used to study morphology of particles and their distribution in the composites. Tensile tests were carried out at room temperature at a strain rate of 1.07 ×10−3 s−1 using a 100 KN screw-driven Instron™ Universal Testing Machine (Model 4206). The bulk hardness of the composites was made by Aktiebolaget Alpha Brinell hardness testing machine. Dry sliding wear test were carried out at room temperature on a pin-on-disk wear and friction tester (DUCOM, Bangalore, India, model: TR20-LE) for various distance and load.

3. RESULTS AND DISCUSSION

Figure 1 shows the XRD pattern of the as cast AA5052 base alloy and composites synthesized from AA5052 alloy and inorganic salts using direct melt reaction method. XRD analysis of peaks indicates the presence of Al, Al(Zr and ZrB2 phase which confirm the successful formation of second phase reinforcement in AA5052 alloy matrix. The possible reactions between the alloy and salts to form the Al(Zr, ZrB2 and Al(Zr+ZrB2 reinforcement particles take place in the following sequence:

3K2ZrF6 +13Al→3Al2Zr+4AlF3+6KF(g)
3K2ZrF6 +6KBF4 +10Al→3ZrB2+9KAlF4+K3AlF11(g)
3K2ZrF6 +2KBF4 +12Al→ZrB2+2Al3Zr+2KAlF4+4AlF3+6KF(g)

Figures 2a-d show the SEM micrographs of composites. Al(Zr particles are uniformly distributed in the alloy matrix in two shapes namely, polyhedron and rectangular in micron size as shown in Fig. 2a. ZrB2 particles are uniformly distributed in hexagon and rectangular shapes in nano to micron size as evident
from Fig. 2b and Fig. 2c at higher magnification. Figure 2d indicates the presence of Al$_2$Zr and cluster of ZrB$_2$ particles.

Table 2 shows the tensile properties and hardness of composites and base alloy. It is observed that with incorporation of Al$_2$Zr and ZrB$_2$ particles in base alloy, tensile properties are improved when reinforced with different particles and it is highest in case of Al$_2$Zr + ZrB$_2$ reinforced composite. It is interesting to note that %elongation of all composites is superior to base alloy.

Figures 3a-b show the variation of wear rate and average coefficient of friction for base alloy and composites with different reinforcements at 40 N normal load and 1 m/s sliding velocity. The Bulk wear continuously increase with sliding distance but with incorporation of reinforcement bulk wear decreases, however, a fluctuating tendency is observed in case of coefficient of friction with sliding distance as observed in Fig. 4b. Figures 5a-b show the variation of wear rate and coefficient of friction for all compositions at 1 m/s sliding velocity. Minimum wear rate is observed in the (Al$_2$Zr+ZrB$_2$)/AA5052 composite (Fig. 5a), whereas coefficient of friction is higher (Fig. 5b) as compare to other composites and base alloy.

4. CONCLUSION

From the present study, the following conclusions may be drawn:
1) The AA5052 base composites reinforced with Al$_2$Zr, ZrB$_2$ and Al$_2$Zr+ZrB$_2$ can be successfully fabricated by DMR route.
2) The Al$_2$Zr particles are in polyhedron and rectangular shapes, while ZrB$_2$ particles are in hexagonal and rectangular shapes.
3) Maximum improvement in UTS and YS is observed in the Al$_2$Zr+ZrB$_2$ reinforced composite.
4) Percentage elongation in all composites is higher than base alloy.
5) Cumulative weight loss and wear rate increases with increase in the sliding distance and normal load.
6) Minimum wear rate is observed in the (Al\textsubscript{3}Zr+ZrB\textsubscript{2})/AA5052 composite, while coefficient of friction is higher.
